# System.Text.Json Namespace

The System.Text.Json namespace provides high-performance, low-allocating, and standards-compliant capabilities to process JavaScript Object Notation (JSON), which includes serializing objects to JSON text and deserializing JSON text to objects, with UTF-8 support built-in. It also provides types to read and write JSON text encoded as UTF-8, and to create an in-memory document object model (DOM) for random access of the JSON elements within a structured view of the data.

## Classes

<a href="#">JsonDocument</a>	Provides a mechanism for examining the structural content of a JSON value without automatically instantiating data values.
<a href="#">JsonException</a>	Defines a custom exception object that is thrown when invalid JSON text is encountered, when the defined maximum depth is passed, or the JSON text is not compatible with the type of a property on an object.
<a href="#">JsonNamingPolicy</a>	Determines the naming policy used to convert a string-based name to another format, such as a camel-casing format.
<a href="#">JsonSerializer</a>	Provides functionality to serialize objects or value types to JSON and to deserialize JSON into objects or value types.
<a href="#">JsonSerializerOptions</a>	Provides options to be used with <a href="#">JsonSerializer</a> .
<a href="#">Utf8JsonWriter</a>	Provides a high-performance API for forward-only, non-cached writing of UTF-8 encoded JSON text.

## Structs

<a href="#">JsonDocumentOptions</a>	Provides the ability for the user to define custom behavior when parsing JSON to create a <a href="#">JsonDocument</a> .
<a href="#">JsonElement</a>	Represents a specific JSON value within a <a href="#">JsonDocument</a> .
<a href="#">JsonElement.ArrayEnumerator</a>	Represents an enumerator for the contents of a JSON array.
<a href="#">JsonElement.ObjectEnumerator</a>	Represents an enumerator for the properties of a JSON object.
<a href="#">JsonEncodedText</a>	Provides methods to transform UTF-8 or UTF-16 encoded text into a form that is suitable for

Thank you.

# JSON

# JSON

# System.Text.Json

Released in 2019 with .NET Core 3.0

Provide high-performance JSON APIs

- Use of new functionality, like `Span<T>`
- Use UTF-8 instead of UTF-16

Remove Json.NET dependency

- From ASP.NET Core
- Moved to a separate package

JSON has become an essential part of virtually all modern .NET applications and in many cases even surpassed the usage of XML. However, .NET hasn't had a (great) built-in way to deal with JSON. Instead we've relied on [Json.NET](#) which continues to serve the .NET ecosystem well.

Moving forward, we plan on making some changes to our JSON support:

- **We need high-performance JSON APIs.** We need a new set of JSON APIs that are highly tuned for performance by using `Span<T>` and allows for processing UTF-8 directly without having to transcode to UTF-16 `string` instances. Both aspects are critical for our web server Kestrel, where throughput is a key requirement.
- **Remove dependency from ASP.NET Core to Json.NET.** Today, ASP.NET Core has a dependency on Json.NET. While this provides a tight integration between ASP.NET Core and Json.NET, it also means that application developers cannot freely choose which JSON library they are using. This is also problematic for customers of Json.NET as the version is dictated by the underlying platform. However, Json.NET is frequently updated and application developers often want to -- or even have to -- use a specific version. Thus, we want to remove the dependency from ASP.NET Core 3.0 to Json.NET so that customers can choose which version to use, without fearing they might accidentally break the underlying platform. In addition, this makes it also possible to plug-in an entirely different JSON library.
- **Provide an ASP.NET Core integration package for Json.NET.** Json.NET has basically become the Swiss Army knife of JSON processing in .NET. It provides many options and facilities that allow customers to handle their JSON needs with ease. We don't want to compromise on the Json.NET support customers are getting today, for example, the ability to configure the JSON serialization via the `AddJsonOptions` extension method. Thus, we want to provide the Json.NET integration as a NuGet package that developers can optionally install so they get all the bells and whistles they get from Json.NET today. The other part of this work item is to ensure we have the right extension points so that other parties can provide similar integration packages for their JSON library of choice.

Json.NET was created over 10 years ago, and since then it has added a wide range of features aimed to help developers work with JSON in .NET. In that time Json.NET has also become far and away NuGet's most depended on and downloaded package, and is the go-to library for JSON support in .NET. Unfortunately, Json.NET's wealth of features and popularity works against making major changes to it. Supporting new technologies like `Span<T>` would require fundamental breaking changes to the library and would disrupt existing applications and libraries that depend on it.

**James Newton-King says...**

Going forward Json.NET will continue to be worked on and invested in, both addressing known issues today and supporting new platforms in the future. Json.NET has always existed alongside other JSON libraries for .NET, and there will be nothing to prevent you using one or more together, depending on whether you need the performance of the new JSON APIs or the large feature set of Json.NET.

# How to migrate from Newtonsoft.Json to System.Text.Json

01/10/2020 • 32 minutes to read • 

This article shows how to migrate from [Newtonsoft.Json](#) to [System.Text.Json](#).

The `System.Text.Json` namespace provides functionality for serializing to and deserializing from JavaScript Object Notation (JSON). The `System.Text.Json` library is included in the [.NET Core 3.0](#) shared framework. For other target frameworks, install the [System.Text.Json](#) NuGet package. The package supports:

- .NET Standard 2.0 and later versions
- .NET Framework 4.7.2 and later versions
- .NET Core 2.0, 2.1, and 2.2

`System.Text.Json` focuses primarily on performance, security, and standards compliance. It has some key differences in default behavior and doesn't aim to have feature parity with `Newtonsoft.Json`. For some scenarios,

`System.Text.Json` has no built-in functionality, but there are recommended workarounds. For other scenarios, workarounds are impractical. If your application depends on a missing feature, consider [filing an issue](#) to find out if support for your scenario can be added.

Most of this article is about how to use the [JsonSerializer](#) API, but it also includes guidance on how to use the [JsonDocument](#) (which represents the Document Object Model or DOM), [Utf8JsonReader](#), and [Utf8JsonWriter](#) types.

## Table of differences between Newtonsoft.Json and System.Text.Json

The following table lists `Newtonsoft.Json` features and `System.Text.Json` equivalents. The equivalents fall into the following categories:

Thank you.

# Table of differences between Newtonsoft.Json and System.Text.Json

The following table lists `Newtonsoft.Json` features and `System.Text.Json` equivalents. The equivalents fall into the following categories:

- Supported by built-in functionality. Getting similar behavior from `System.Text.Json` may require the use of an attribute or global option.
- Not supported, workaround is possible. The workarounds are [custom converters](#), which may not provide complete parity with `Newtonsoft.Json` functionality. For some of these, sample code is provided as examples. If you rely on these `Newtonsoft.Json` features, migration will require modifications to your .NET object models or other code changes.
- Not supported, workaround is not practical or possible. If you rely on these `Newtonsoft.Json` features, migration will not be possible without significant changes.

Newtonsoft.Json feature	System.Text.Json equivalent
Case-insensitive deserialization by default	✔ <a href="#">PropertyNameCaseInsensitive</a> global setting
Camel-case property names	✔ <a href="#">PropertyNamePolicy</a> global setting
Minimal character escaping	✔ <a href="#">Strict character escaping</a> , configurable
<code>NullValueHandling.Ignore</code> global setting	✔ <a href="#">IgnoreNullValues</a> global option
Allow comments	✔ <a href="#">ReadCommentHandling</a> global setting
Allow trailing commas	✔ <a href="#">AllowTrailingCommas</a> global setting
Custom converter registration	✔ <a href="#">Order of precedence differs</a>
No maximum depth by default	✔ <a href="#">Default maximum depth 64</a> , configurable
Support for a broad range of types	⚠ <a href="#">Some types require custom converters</a>

Thank you.
